VULNERABILITY ASSESSMENT & SECURITY RISK DASHBOARD

ABSTRACT

The Vulnerability Assessment and Security Risk Dashboard is a cybersecurity project designed to identify and organize security weaknesses in computer systems and web applications. Organizations may have multiple systems with different vulnerabilities, making it difficult to understand which security issues should be fixed first. The proposed system collects vulnerability information from authorized security scans and analyzes the findings based on factors such as severity, affected service, vulnerability type, and possible impact. The results are presented through a user-friendly dashboard where security analysts can view the total number of vulnerabilities, critical and high-risk issues, affected systems, and the current security status. Vulnerabilities can be grouped according to categories such as outdated software, insecure configurations, exposed services, and web application weaknesses. The system can also provide recommendations for addressing important findings and generate a security assessment report. A risk-based priority system helps users focus on the vulnerabilities that require immediate attention. The main goal of this project is to make vulnerability assessment easier to understand and help organizations prioritize security issues so that important weaknesses can be addressed before they are exploited.
